

Moles

MOLE MANAGEMENT PROGRAM

The Eastern Mole is the most common mole and can create chaos in your lawn and landscaping. Moles are generally more active in late winter and early spring when breeding is at its peak. However, moles do not hibernate, they remain active all year long and are very territorial.

The #1 food source for moles is earthworms, which make up about 90% of their diet followed by grubs, which make up about 5% of their diet. Moles find their meal by feeling the vibration of the earthworm moving through the soil.

Did you know?

- ***Moles typically eat between 80-100% of their body weight everyday.***
- ***Moles can create 15-18 feet of tunnels per hour.***
- ***Moles can travel 80 feet per minute in existing tunnels.***
- ***Moles can reinvade existing runs in your yard.***

Treatment

Contrary to popular belief, baits, sonic chasers, repellants, mothballs and home remedies have no effect on moles. OPC will use an attractive and palatable bait called "Talpirid" which is scientifically proven to kill moles. The bait is designed to mimic an earthworm that can be easily identified by the mole. We will use a 3-Step Process to provide a cost effective treatment method.

Step 1: OPC will visit the property to map and evaluate the site to determine which runs are active.

Step 2: OPC will revisit the site to place bait that mimic the earthworm in the active runs.

Step 3: Follow-up services will be performed to evaluate the results and determine if future baiting needs to occur.

We also provide solutions for:

Ants | Spiders | Roaches | Rodents | Termites | Bed Bugs | Mosquitoes | Birds | Bats | Bees | Fleas

Louisville | Lexington | Indianapolis
